74HC/HCT4352 Dual 4-channel analog multiplexer/demultiplexer with latch

Product specification
File under Integrated Circuits, IC06

December 1990

74HC/HCT4352

FEATURES

• Wide analog input voltage range: ± 5 V.

• Low "ON" resistance:

80 Ω (typ.) at $V_{CC} - V_{EE} = 4.5 \text{ V}$

70 Ω (typ.) at $V_{CC} - V_{EE} = 6.0 \text{ V}$

 60Ω (typ.) at $V_{CC} - V_{EE} = 9.0 \text{ V}$

 Logic level translation: to enable 5 V logic to communicate with ± 5 V analog signals

• Typical "break before make" built in

· Address latches provided

· Output capability: non-standard

I_{CC} category: MSI

GENERAL DESCRIPTION

The 74HC/HCT4352 are high-speed Si-gate CMOS devices. They are specified in compliance with JEDEC standard no. 7A.

The 74HC/HCT4352 are dual 4-channel analog multiplexers/demultiplexers with common select logic.

Each multiplexer has four independent inputs/outputs $(nY_0 \text{ to } nY_3)$ and a common input/output (nZ).

The common channel select logics include two select inputs (S_0 and S_1), an active LOW enable input (\overline{E}_1), an active HIGH enable input (E_2) and a latch enable input ($\overline{\text{LE}}$).

With \overline{E}_1 LOW and E_2 HIGH, one of the four switches is selected (low impedance ON-state) by S_0 and S_1 . The data at the select inputs may be latched by using the active LOW latch enable input (\overline{LE}). When \overline{LE} is HIGH, the latch is transparent. When either of the two enable inputs, \overline{E}_1 (active LOW) and E_2 (active HIGH), is inactive, all analog switches are turned off.

 V_{CC} and GND are the supply voltage pins for the digital control inputs (S $_0$, S $_1$, \overline{LE} , \overline{E}_1 and E $_2$). The V $_{CC}$ to GND ranges are 2.0 to 10.0 V for HC and 4.5 to 5.5 V for HCT. The analog inputs/outputs (nY $_0$ to nY $_3$, and nZ) can swing between V $_{CC}$ as a positive limit and V $_{EE}$ as a negative limit. V $_{CC}$ – V $_{EE}$ may not exceed 10.0 V.

For operation as a digital multiplexer/demultiplexer, V_{EE} is connected to GND (typically ground).

QUICK REFERENCE DATA

 $V_{EE} = GND = 0 \text{ V}; T_{amb} = 25 \,^{\circ}\text{C}; t_r = t_f = 6 \text{ ns}$

| SYMBOL | PARAMETER | CONDITIONS | TYP | UNIT | | |

| | common (Z) | | 12 | 12 | pF | |

Notes

1. C_{PD} is used to determine the dynamic power dissipation (P_D in μW):

 $P_D = C_{PD} \times V_{CC}^2 \times f_i + \sum \{ (C_L + C_S) \times V_{CC}^2 \times f_o \}$ where:

f_i = input frequency in MHz

f_o = output frequency in MHz

 $\sum \{ (C_L + C_S) \times V_{CC}^2 \times f_o \} = \text{sum of outputs}$

 C_L = output load capacitance in pF

C_S = max. switch capacitance in pF

V_{CC} = supply voltage in V

2. For HC the condition is $V_I = GND$ to V_{CC} For HCT the condition is $V_I = GND$ to $V_{CC} - 1.5$ V

Note

1. To avoid drawing V_{CC} current out of terminals nZ, when switch current flows in terminals nY_n, the voltage drop across the bidirectional switch must not exceed 0.4 V. If the switch current flows into terminals nZ, no V_{CC} current will flow out of terminals nY_n. In this case there is no limit for the voltage drop across the switch, but the voltages at nY_n and nZ may not exceed V_{CC} or V_{EE} .

Notes

- At supply voltages (V_{CC} V_{EE}) approaching 2.0 V the analog switch ON-resistance becomes extremely non-linear.
 There it is recommended that these devices be used to transmit digital signals only, when using these supply voltages.

Notes

- 1. Adjust input voltage V_{is} to 0 dBm level (0 dBm = 1 mW into 600 Ω).
- 2. Adjust input voltage V_{is} to 0 dBm level at V_{os} for 1 MHz (0 dBm = 1 mW into 50 Ω).

 V_{is} is the input voltage at an nY_n or nZ terminal, whichever is assigned as an input. V_{os} is the output voltage at an nY_n or nZ terminal, whichever is assigned as an output.
